The source or collection of income variables

procedure used for the Collection of income variables at component level have been obtained. The method used for obtaining target variables in

the required form

The source for the collection of income variables was paper and pencil interviews for all income variables, including the money

the selfemployed. We did not used administrative

records. The use of the justificative documents

regarding the incomes was the respondents' decision.

drawn out of business by The majority of income components were recorded net and the gross variables were obtained by adding at the net values, the value of income tax retained at source and social contributions paid (in the case of wages, we add the value of other sums retained at source, too).

The only income components calculated in the process of data editing were:

- the value of income tax retained at source for salaries (we have a flat rate of 16% for income tax), the respondents being asked only if they paid or not the income tax for wage;
- the exact value of the social insurance contribution retained at source for salaries, if this was declared in the form of an interval.
- the value of income tax retained at source and social insurance contributions for pensions (if the pension was bigger than 1000 lei);
- the interest for dividends and money withdrawn from the banks.

## 3. Statistical processing

Top

Detailed information concerning sampling frame, sampling design, sampling units, sampling size, weightings and mode of data collection can be found in this section. Such information is mainly used for the computation of the accuracy measures.

## 3.1. Source data

Starting with 2015, the household surveys carried out by NSI-Romania are based on the use of Multifunctional Sample of Territorial Areas, so called the master sample new EMZOT. It is a database including approximately 1.500.000 dwellings, selected according to probabilistic criteria, serving as sampling frame for all household surveys, in 2015-2024.

For the wave 1, wave 2 and wave3 (subsample selected in 2015, 2016 and 2017), a master sample database named "new EMZOT" is used. In the first stage, a stratified random sample of 792 areas, Primary Sampling Units (PSUs), was designed after the 2011 Population and Dwelling Census. The PSUs were sampled with probability proportional to the size (number of permanent dwellings). The new EMZOT sample has 450 PSUs selected from urban area and 342 PSUs selected from rural area. In the second stage, a fix number of dwellings are systematically selected from each PSU of EMZOT.

For the last wave (2014), a master sample database named "old EMZOT" was used. In the first stage, a stratified random sample of 780 areas, Primary Sampling Units (PSUs), was designed after the 2002 Census. The PSUs were sampled with probability proportional to the size (number of permanent dwellings). The

EMZOT sample has 427 PSUs selected from urban area and 353 PSUs selected from rural area. In the second stage, a fix number of dwellings are systematically selected from each PSU of EMZOT.

## 3.1.1. Sampling

Type of sampling design

The sampling plan is a two-stage probability sampling of housing units (dwellings).

Stratification and sub stratification criteria

Stratification concerns only the first stage sampling. There are 88 strata, the criteria used being the area where a certain PSU is located (urban or rural area) and county (NUTS 3 level).

Sample selection schemes

The survey uses the integrated four years rotational panel design, in which one-fourth of the sample is replaced each year. The total sample for the year 2017 is made by the sub-samples S3, S4, S1 and S2.

				Years							
	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017

							S2	S2	S2	S2	
								<b>S3</b>	S3	S3	S3
									<b>S4</b>	S4	S4
										<b>S1</b>	S1
											S2

Sample distribution over time

The sample is not distributed over time.

### 3.1.2. Sampling unit

The Primary Sampling Unit, corresponding to the selection of the *master sample*, is a group of Census sections (census enumeration areas EAs). The Secondary (ultimate) Sampling Unit, corresponding to the selection of the survey sample, is the dwelling.

## 3.1.3. Sampling frame

Concerning the SILC instrument, three different sample size definitions can be applied:

- the actual sample size which is the number of sampling units selected in the sample
- the achieved sample size which is the number of observed sampling units (household or individual) with an accepted interview
- the effective sample size which is defined as the achieved sample size divided by the design effect with regards to the at-risk-of poverty rate indicator Given that the effective sample size has been already treated in the section dealing with sampling errors, in this section the attention focuses mainly on the achieved sample size.

Actual and achieved sample size

Achieved sample size

- sample persons	11695
- co-residents	178

## 3.2. Frequency of data collection

Frequency of data collection is annually.

## 3.3. Data collection

Data collection period was 8 – 26 May 2017.

### Mode of data collection

The method of data collection was face-to-face personal interviews, using paper questionnaires. The interviewers visited the addresses selected in the sample and fulfilled the questionnaires, based on the interviews. The household questionnaire was fulfilled by interview with the household head and individual questionnaire by interview with each household member 16 years old and more.

## The mean interview duration

The mean interview duration per household is calculated as the sum of the duration of all household interviews plus the sum of the duration of all personal interviews, divided by the number of household questionnaires completed. Only households accepted for the database have to be considered. Average interview duration = 59.0 minutes.

level using the household variables and individual variables in their aggregate form as calibration variables. This technique ensures that all members in the same household receive the same weight. Adjustments were made using the SAS macro CALMAR. Calibration variables were:

"distribution of the population by age group (0-15; 16-24;

were calculated: Household cross-

sectional

Wave 1(subsample selected in 2017) The design factor of the household is the inverse of inclusion probability. The design factor for households and for individuals are the same, because in each selected

In order to contra balance the non-respondent households, it We applied an integrative calibration that means that we is proceed at a re-weighting, by adjusting the weights of the used both households and personal variables in the respondent households with the inverse of the response rate. procedure. The calibration is performed at the household The non-response are not globally adjusted, at the entire sample level, but separately-at wave level, on groups of households, groups generated by the variables considered as explicative of the non response. This correspond to the so-called 'response-homogenous groups' method, which assumes that in a certain group all the units have the same probability. For wave 1 we used as explicative variables for non-response region (NUTS II level) and area of residence

Design factor dwelling, all persons are selected for the survey. In case of the households at the second, third and four wave, an indirect sampling of households is done through the panel (of persons aged 14+ at the time of the panel selection). In this case, the inclusion probabilities cannot be calculated. Then, the solution consists of applying the Weight Share Method. Wave 2 (subsample selected in 2016) The design factors of households are calculated through the individual base weights. The individual base weights

selected in 2015)
There are two situations:

Wave 3 (subsample

are obtained from crosssectional weights calculated in previous year inflated with attrition.

a. The sample person was a respondent in 2016. The base weight is calculated taking into account the base weight of previous year and then corrected both: attrition between 2016 and 2017 and compensation of the reentrees.

b. The sample person was a non-respondent in 2016

(re-entrees). In this case the base weight is obtain taking into account the cross-sectional weight RB050 calculated in 2015 corrected for the attrition between 2015-2017. Wave 4 (subsample selected in 2014)

The approach is similar with the previous wave and two cases are distinguished, too:

a. The sample person was a respondent in

2016. The base weight

taking into account the base weight of previous year and then corrected

is calculated

both: attrition

(urban / rural) and for the second, third and fourth wave the region. In order to minimize the effects induced by the presence of non-response another adjustment is done: reweighting by calibration of the weights.

Non-response adjustments

Adjustment to external data

25-34; 35-44; 45-54; 55-64; 65 and over) and gender" using weight Romanian Residential Population Estimates at the end of the (DB090) income reference period and "households totals" by region. 2)

taken into account.

6. Accuracy and reliability

Top

The concept of accuracy refers to the precision of estimates computed from a sample rather than from the entire population. Accuracy depends on sample size, sampling design effects and structure of the population under study. In addition to that, sampling errors and non sampling errors need to be taken into account. Sampling error refers to the variability that occurs at random because of the use of a sample rather than a census and non-sampling errors are errors that occur in all phases of the data collection and production process.

#### 6.1. Accuracy - overall

In terms of precision requirements, the EU-SILC framework regulation as well the Commission Regulation on sampling and tracing rules refers respectively, to the effective sample size to be achieved and to representativeness of the sample. The effective sample size combines sample size and sampling design effect which depends on sampling design, population structure and non-response rate.

### 6.2. Sampling error

EU-SILC is a complex survey involving different sampling design in different countries. In order to harmonize and make sampling errors comparable among countries, Eurostat (with the substantial methodological support of Net-SILC2) has chosen to apply the "linearization" technique coupled with the "ultimate cluster" approach for variance estimation. Linearization is a technique based on the use of linear approximation to reduce non-linear statistics to a linear form, justified by asymptotic properties of the estimator. This technique can encompass a wide variety of indicators, including EU-SILC indicators. The "ultimate cluster" approach is a simplification consisting in calculating the variance taking into account only variation among Primary Sampling Unit (PSU) totals. This method requires first stage sampling fractions to be small which is nearly always the case. This method allows a great flexibility and simplifies the calculations of variances. It can also be generalized to calculate variance of the differences of one year to another.

The main hypothesis on which the calculations are based is that the "at risk of poverty" threshold is fixed. According to the characteristics and availability of data for different countries we have used different variables to specify strata and cluster information. In particular, countries have been split into four groups:

1)BE, BG, CZ, IE, EL, ES, FR, IT, LV, HU, NL, PL, PT, RO, SI, UK and HR whose sampling design could be assimilated to a two stage stratified type we used DB050 (primary strata) for strata specification and DB060 (Primary Sampling Unit) for cluster specification;

- 2) DE, EE, CY, LT, LU, AT, SK, FI, CH whose sampling design could be assimilated to a one stage stratified type we used DB050 for strata specification and DB030 (household ID) for cluster specification;
- 3) DK, MT, SE, IS, NO, whose sampling design could be assimilated to a simple random sampling, we used DB030 for cluster specification and no strata; Sampling errors were calculated for the common cross-sectional EU indicators based on the cross-sectional component of EU-SILC. Particularly, sampling errors were estimated with the JRR method using the software developed by Siena University (EUSILC-Report 06 for the Intermediary Quality).

### 6.3. Non-sampling error

Non-sampling errors are basically of 4 types:

- Coverage errors: errors due to divergences existing between the target population and the sampling frame.
- Measurement errors: errors that occur at the time of data collection. There are a number of sources for these errors such as the survey instrument, the information system, the interviewer and the mode of collection
- · Processing errors: errors in post-data-collection processes such as data entry, keying, editing and weighting
- · Non-response errors: errors due to an unsuccessful attempt to obtain the desired information from an eligible unit. Two main types of non-response errors are considered:
- 1. Unit non-response: refers to absence of information of the whole units (households and/or persons) selected into the sample
- 1. Item non-response: refers to the situation where a sample unit has been successfully enumerated, but not all required information has been obtained

Due to the lack of appropriate information, the new dwellings, built after 2011 Census of the Population and Dwellings have not been taken into account.

#### 6.3.1. Coverage error

Coverage errors include over-coverage, under-coverage and misclassification:

- Over-coverage: relates either to wrongly classified units that are in fact out of scope, or to units that do not exist in practice
- Under-coverage: refers to units not included in the sampling frame
- Misclassification: refers to incorrect classification of units that belong to the target population

Over-coverage rate was estimated on the basis of the survey sample, as ratio between number of not-eligible dwellings (not-existing addresses, or being nonresidential or unoccupied or not the main addresses) and number of sampled dwellings (all addresses selected). Over-coverage rate was 2.15%.

Under-coverage rate was estimated as the ratio between number of new dwellings, built in the period end of 2011 year (the year of the census) - end of 2016 year and number of dwellings at the end of 2016 year (Source: Romanian Statistical Yearbook, 2017). Thus, it was assumed that the proportion of the new dwellings in total dwellings should be the same in the master sample. Under-coverage rate was 2.59%.

## 6.3.1.1. Over-coverage - rate

	Main problems	Size of error
	Over-coverage	
~		2.15%
Cross sectional data	•Under-coverage	2.59%
	•Misclassification	

## 6.3.1.2. Common units - proportion

## 6.3.2. Measurement error

Cross sectional data

As in any other survey, We used three types of there are 3 questionnaires:	Source of measurement errors	Building process of questionnaire
main sources of - the household file; of measurement errors: - the household questionnaire, with the detailed questions regarding the household;	other survey, there are 3 main sources of measurement	questionnaires: - the household file; -the household questionnaire, with the detailed questions regarding the

- the individual questionnaire, which - the was fulfilled for each person 16 questionnaires years or more, in order to record (1) better the incomes of the people less - the than 16 years. interviewers

The questionnaires were up-dated (2) with the improvements based on the - the respondents

survey conclusions and the 2017 (3) secondary module. The structure of questionnaires was

the following:

The main challenge for the interviewers in the seventh wave was to administer the tracing rules. Beside this, the recording of the accurate incomes was the second very difficult task. A social insurance contribution and the taxes on handbook was prepared with all the information available to help the interviewers in the fields work activities. Explanations for a big number of questions from all the questionnaires were included. Aspects related to the follow-up they were asked what kind of housing cost of households/persons and the construction of identifiers was explained in this handbook also. A special section included some recommendations about the behavior in the respondents' elements of the housing cost are presence and the way the interviewers should convince population to participate to this survey. Other aspects: Some interviewers used very seldom some household identification numbers for the households and individuals from the new sub-sample, which were overlapped with some old households from the subsamples which left the survey in 2014 and 2015; all these identification numbers were corrected.

Interview training

## Quality control

For respondents, the most difficult information to declare was the value of incomes in the previous calendar year, the wealth. Another difficult answer was related to the housing cost, also the question was preceding by a helping question in which that household is actually paying, in order to be sure the respondent is thinking at the recommended by EU-SILC methodology to be included here.

Another aspect which created some problems was the co-relation between the declaration of the marital status/consensual union between partners. There were cases in which one partner declared he is married and his/her partner declared he is in consensual union. These case were solved by taking with Cross sectional data

## Source of

## measurement Building process of questionnaire errors

### The household file included:

- identification data;
- the household composition
- name, identificator, date of birth, sex, the relatives' code (mother's, father's and husband's/wife's), sample-person or co-resident, person's mobility compared with first wave, month and year when the current person left the household/came into the sampled household (if was the case), economic status during the income reference period etc.;
- some questions about household identification; the household file is design and used all four years a person is included in the survey.

## The household questionnaire included:

- -identification data;
- -data regarding child care for all the children less than 13 years;
- data regarding access services;
   -questions regarding economic
   situation of the household (housing and non-housing related arrears, non-monetary household deprivation questions);
   endowment with durable goods;
- -housing conditions including questions regarding information about dwelling installations and facilities, accessibility of basic needs, change of the dwelling, dwelling and dwelling environment, housing cost, amenities in the dwelling;
- -taxes paid at household level for the year 2016;
- -household incomes in 2016.

## The individual questionnaire:

- -identification data;
- -questions regarding de jure and de facto marital status; first and second citizenships; country of birth; year of immigration in Romania;
- -questions regarding the health status; limitations in activities due to a medical problem; unmeet need for medical, respectively dental consultation; reasons for the unmeet need for medical and dental consultation;
- -level of education questions (the school attended currently, the highest level of education attended and the year when the person graduated this level);
- -questions regarding the 2017 secondary module (Module on

#### Interview training

#### Quality control

priority the idea of a consensual union in the case the partners have not the same family

Some households found difficult to estimate the rent they would receive if they would rent the dwelling.

## measurement Building process of questionnaire errors

**Interview training** 

Quality control

Health and Children's Health);
-questions regarding detailed
information about employment/nonemployment;

-individual incomes achieved in 2016.

In order to help the data collection activities, other materials were designed by the methodological team:

-the letter for the households — a paper sheet in which the objectives of the EU-SILC survey is presented, the importance of the people participation is highlighted and the confidentiality of the data is guarantied.

-the list of the dwelling and households included in the sample (LG) is a document with two parts: first one included the exact addressees selected to carry-out the interviews. The second part included the situation found on the field for each address. This document is very useful for the interviewers and supervisors in order to check the integrity of the data collected. -the tracing file, was a paper sheet designed in order to identify households/persons which moved from the initial addresses from the first wave. The paper sheet fulfilled by the county from which they left were sent to the NIS methodological team and they sent again in the county where the information collected show they moved in. These counties proceeded to follow-up and interviewed them, in the case they founded.

#### 6.3.3. Non response error

Non-response errors are errors due to an unsuccessful attempt to obtain the desired information from an eligible unit. Two main types of non-response errors are considered:

- 1) Unit non-response which refers to the absence of information of the whole units (households and/or persons) selected into the sample. According the Commission Regulation 28/2004:
  - Household non-response rates (NRh) is computed as follows:

NRh=(1-(Ra \* Rh)) \* 100

Where Ra is the address contact rate defined as:

Ra= Number of address successfully contacted/Number of valid addresses selected

and Rh is the proportion of complete household interviews accepted for the database

Rh=Number of household interviews completed and accepted for database/Number of eligible households at contacted addresses

• **Individual non-response rates** (*NRp*) will be computed as follows:

NRp=(1-(Rp)) \* 100

Where Rp is the proportion of complete personal interviews within the households accepted for the database

Rp= Number of personal interview completed/Number of eligible individuals in the households whose interviews were completed and accepted for the database

• Overall individual non-response rates (\*NRp) will be computed as follows:

### \*NRp=(1-(Ra \* Rh \* Rp)) \* 100

For those Members States where a sample of persons rather than a sample of households (addresses) was selected, the individual non-response rates will be calculated for 'the selected respondent', for all individuals aged 16 years or older and for the non-selected respondent.

2) Item non-response which refers to the situation where a sample unit has been successfully enumerated, but not all the required information has been obtained.

## 6.3.3.1. Unit non-response - rate

Cross sec	tional dat	ta

<sup>\*</sup> All the formulas are defined in the Commission Regulation 28/2004, Annex II

## 6.3.3.2. Item non-response - rate

The computation of item non-response is essential to fulfil the precision requirements concerning publication as stated in the Commission Regulation No 1982/2003. Item non-response rate is provided for the main income variables both at household and personal level.

We have no item non-response due to the checking programs used at the county level which show these missing data and the supervisors have to solve it: first of all, the questionnaire is checked in order to find if it is an operator's mistake and secondly, the household is asked again if the information was not supplied from the beginning. Finnaly, item non-response imputation is applied, if it is the case.

6.3.4. Processing error

Data entry and coding

Editing controls

Data entry and coding

During the field work period and data processing period several checks were done. Data editing and cleaning was done in two steps: firstly, at the level of each county and secondly, after the counties' files will be sent to INS team, a second check was done by EU-SILC central team. At the county level, after data collection, supervisors had the duty to check the integrity of the questionnaires (one household file and at least one household questionnaire per household and as many personal questionnaires as household members 16 years and more exists). During data entry, checking software was applied at county level. The counties sent the files at central level and a new check was done on the national files. The checking software included 3 types of checks: checks at each questionnaire level (household and personal questionnaires), checks for the correlation between the information included in household and personal questionnaires, and a third type of checks, integrity checks, if all the addresses included in the sample were visited (if questionnaires completed exist for each address included in the sample). Inside each type of questionnaire there were 2 types of logical conditions: to see if all the compulsory questions were fulfilled and to check if the answers were correct (for quantitative variables minimal and maximal limits were established, and for qualitative variables logical conditions were tested). After the data files in the EUROSTAT format were obtained, a third data check was done, using the EUROSTAT software available on Circa user group. The process of cleaning the data took a long time and imposed special efforts both from the county teams and central methodological team in order to obtain the 4 microdata files in Eurostat format, due to the big number of variables and numerous correlations between them. A special kind of difficulties were related to the special codification of the split-off/moved households/persons in the original

## 8. Coherence and comparability

<u>Top</u>

According to the Regulation (EC) No 1177/2003 of the European Parliament and of the Council concerning EU-SILC: "Comparability of data between Member States shall be a fundamental objective and shall be pursued through the development of methodological studies from the outset of EU-SILC data collection, carried out in close collaboration between the Member States and Eurostat".

Although the best way for keeping the comparability of data is to apply the same methods and definitions of variables, small departures of the definitions given by Eurostat are allowed in EU-SILC. In this way, the mentioned Regulation in its article 16th says: "Small departures from common definitions, such as those relating to private household definition and income reference period, shall be allowed, provided they affect comparability only marginally. The impact of comparability shall be reported in the quality reports."

The coherence of two or more statistical outputs refers to the degree to which the statistical processes, by which they were generated, used the same concepts and harmonised methods. A comparison with external sources for all income target variables and the number of persons who receive income from each 'income component' will be provided, where the Member States concerned consider such external data to be sufficiently reliable.

## 8.1. Comparability - geographical

\_

## 8.1.1. Asymmetry for mirror flow statistics - coefficient

-

## 8.1.2. Reference population

Reference population

Private household definition

Household membership

The reference population is all private households and their current members residing in the territory of the Romania at the time of data collection. Persons living in collective households and in institutions are excluded from the target population. Household is defined as a person living alone or a group of persons who live together in the same dwelling and share expenditures including the joint provision of the essentials of living.

We used the same household membership definition as the Eurostat recommended in the document EU-SILC 065.

### 8.1.3. Reference Period

Period for taxes on income and social insurance contributions

Income reference periods used

Reference period for taxes on wealth Lag between the income ref period and current variables

No departure from the common definition. The repayments and receipts for tax adjustment referring to the income taxes recalculated for the global income gained in 2016 and they were collected if there were paid/received during the calendar 2017.

No departure from the common definition.
We used a fixed income reference period of twelvemonth, more exactly the previous calendar year (January – December 2016).

No departure from the common definition.

## 8.2. Comparability - over time

A very exact comparison between incomes from HBS and EU-SILC data is not possible due to some methodological differences, more exactly, differences at the level of income elements collected and included in the EU-SILC.

The differences between these two surveys it is possible to be due to the greater value of the income taxes and social insurance contributions for wages, own account activities and pensions in EU-SILC, where these elements are automatical calculated (if the person declared there were paid). In HBS the person should declare himself the value of these components in the diary.

Revenues were collected in the survey HBS as the reference period this year, while in the EU-SILC survey, the reference period of the revenues is the previous year.

A better comparison can be made between at-risk-of-poverty indicators calculated from both surveys.

	2015	2016
	HBS	EU-SILC
Poverty threshold –lei, for one person annually-	7858	7388
At-risk-of-poverty rate (after all social transfers) -%-	22.2	23.6
Dispersion around the poverty threshold -%-		
- at-risk-of-poverty rate at 40% of median	9.1	12.1
- at-risk-of-poverty rate at 50% of median	15.5	17.6
- at-risk-of-poverty rate at 70% of median	29.0	29.8
Relative median risk-of-poverty	27.8	34.5

gap -%-		
At-risk-of-poverty rate before social transfers -%-		
- including pensions	46.7	47.5
- excluding pensions	26.0	28.3
S80/S20 quartile share ratio	5.5	6.5
Gini Coefficient -%-	31.9	33.1

## 8.2.1. Length of comparable time series

\_

### 8.3. Coherence - cross domain

A very exact comparison between incomes from HBS and EU-SILC data is not possible due to some methodological differences, more exactly, differences at the level of income elements collected and included in the EU-SILC.

The differences between these two surveys it is possible to be due to the greater value of the income taxes and social insurance contributions for wages, own account activities and pensions in EU-SILC, where these elements are automatical calculated (if the person declared there were paid). In HBS the person should declare himself the value of these components in the diary.

A better comparison can be made between at-risk-of-poverty indicators calculated from both surveys.
